2015 Updated Guidelines For The Management of Paracetamol Ingestion

Angela Chiew
Emergency Physician/ Clinical Toxicologist
Prince of Wales Hospital
NSW Poison’s Information Centre
Aims of the guidelines

• Guidelines are sets of non-mandatory rules, principles or recommendations.

• Applying guidelines to individual care is always likely to require judgement

• Information needed to achieve best practice

• Guidelines reduce unacceptable or undesirable variations in practice

• Must be up-to-date to be useful
• Decontamination
• Sustained Release Paracetamol ingestion
• “Massive” overdoses
• Paediatric liquid paracetamol ingestion
• Supratherapeutic ingestion
• Hepatotoxicity
Demographics of paracetamol in Australia

- Graudins (EMA 2015): 2009-2013:
  - 647 presentations:
  - 272 (42%) required NAC:
    - Of those requiring NAC median dose 18g (12-25g),
    - mean first concn 1100µmol/L (950-1225µmol/L) - average time to first 5 hours
  - 981 pts:
    - 748 non toxic,
    - 62 > 150mg/L (1000µmol/L),
    - 51 > 200mg/L (1300µmol/L),
    - 49 high risk (300mg/L/2000µmol/L),
    - 40 presented > 24hrs post

### Recommendations of when to seek further advice from Poisons Information Centre.

- **Very large overdoses**: Immediate release or modified release paracetamol overdoses of > 50g or 1g/kg (whichever is lower), OR a very high paracetamol concentration, more than double the nomogram line.
- **Intravenous paracetamol errors/overdoses**.
- **Patients with hepatotoxicity** (e.g., ALT > 1000 IU/L).

**Note**: These are situations where the risk of hepatotoxicity may be greater, the optimum advice is potentially changing and where it may be most useful to seek advice.

### Notes:

- *Cooperative adult patients who have potentially ingested greater than 10g or 200mg/kg, whichever is less. For paracetamol ingestions > 30g activated charcoal should be offered until 4 hours post-ingestion.
- †If paracetamol concentration will not be available until > 8 hours post-ingestion, commence acetylcysteine while awaiting paracetamol concentration.
- ‡Those patients with initial paracetamol concentrations more than double the nomogram line may benefit from an increase in acetylcysteine dose (see text) and a serum paracetamol and ALT concentrations should be checked at the end of the acetylcysteine infusion.
- §Patients should be advised that if they develop abdominal pain, nausea or vomiting further assessment is required.
Activated charcoal should be offered to a cooperative patient:

- **Immediate release paracetamol:**
  - Within 2 hours of paracetamol ingestion in those who have ingested > 10g or 200mg/kg which ever is less

- **Sustained release:**
  - Within 4 hours of ingestion in those who have ingested > 10g or 200mg/kg which ever is less
  - In massive overdoses absorption may continue for up to 24 hours, so patients will likely benefit from activated charcoal even beyond 4 hours

- **> 30g of paracetamol ingested:**
  - Activated charcoal should be offered til 4 hours post ingestion.
Activated Charcoal

- Buckley et al: 15% of those presenting within 2 hours who were given charcoal had a paracetamol concentration above the nomogram line compared to 41% of those who did not receive gastrointestinal decontamination.
- Cohort study of more than 4500 overdose patients - 71 (1.6%) developed aspiration pneumonitis. Emesis, seizure and altered mental status were among the independent predictors of aspiration but NOT the administration of AC.
- AC RCT: adults allocated to treatment with AC consumed 83% of their first dose.
- Studies suggest that the incidence of charcoal associated emesis is considerably lower, of the order of 6–7%.

“Massive” Paracetamol Ingestion

- > 30g paracetamol ingested offer activated charcoal til 4 hours post ingestion if co-operative.

- IV acetylcysteine adjustment:
  - Patients who have a paracetamol concentration **more than double the nomogram line**
  - Consider increasing the dose of acetylcysteine in the 100mg/kg over 16 hours infusion (3rd bag) -that is double dose to 200mg/kg IV NAC over 16 hours

- Near the completion of IV acetylcysteine:
  - check ALT and paracetamol concn
  - Acetylcysteine should be continued if they have an ALT >50U/L or a paracetamol greater than 10mg/L (66µmol/L).
Massive Paracetamol Overdose

- Delayed and erratic absorption may be seen in massive overdose
- Can have elevated paracetamol levels at 24 hours post overdose
Hepatotoxicity despite early treatment

Australian Data:
- Australian Paracetamol Project/ HATS and POWH.
- 145 massive paracetamol overdoses ingestion > 40g
- 5 patients treated within 8h developed hepatotoxicity – 1 required a transplant.
- Those receiving activated charcoal had significantly lower levels.

Graph: % hepatotoxicity, after Rx with oral NAC. Study of 2540 people

The original acetylcysteine dosing was conceived to detoxify the paracetamol toxic metabolite NAPQI, based on a 4% conversion rate.

“Standard” dosing might be insufficient in the setting of massive ingestion.

Severely poisoned patients a higher proportion of the dose undergoes conversion to NAPQI.

Suggest a dual approach:
- Prolonged IV acetylcysteine
- Increase in dose of IV acetylcysteine

**Doubling the third dose of IV NAC international survey:** 164 responses, 19 countries - most would increase NAC dose, 33% choose 3000umol/L as the cut of
Modified release paracetamol

- In those who have ingested > 10g or 200mg/kg whichever is less – commence acetylcysteine
- Acetylcysteine may be discontinued:
  - if serial levels, taken 4 hours apart are below the nomogram line and are decreasing.
- Near the completion of N-acetylcysteine the patient should have a repeat ALT and paracetamol concentration.
- Acetylcysteine should be continued if the ALT is increasing or paracetamol concentration is greater than 10mg/L (66µmol/L).
**Supra-therapeutic Ingestion**

- Patients should have a paracetamol level and ALT measured if they meet the criteria for supratherapeutic ingestion.

- Criteria for supratherapeutic ingestion:
  - more than 10 g or 200 mg/kg (whichever is less) in a single 24-hour period
  - more than 6 g or 150 mg/kg (whichever is less) per 24 hours for the preceding 48-hours
  - more than 4g/day or 100 mg/kg/day (whichever is less) for more than 48 hours, in those who also have abdominal pain, nausea and vomiting

---

**Flowchart for Assessment and Management of Supratherapeutic Ingestion**

- Does the patient meet the criteria for repeated supratherapeutic ingestion?
  - Yes: Measure serum paracetamol concentration and ALT
  - No: No further management required

**Criteria for Adults and Children 6+ years**
- more than 10g or 200mg/kg (whichever is lower) in a single 24-hour period
- more than 6g or 150mg/kg (whichever is lower) per 24 hours for the preceding 48-hours
- more than 4g/day or 100mg/kg/day (whichever is lower) for more than 48 hours in those who also have abdominal pain, nausea and vomiting

**Criteria for Children < 6 years**
- 200mg/kg or more in a single 24-hour period
- 150mg/kg or more per 24-hour period for the preceding 48-hours
- 100mg/kg/day or more per 24-hour period for more than 48 hours

**Note:** For obese children, the weight used should be based on an ideal body weight.

** ALT < 50U/L, and serum paracetamol concentration less than 20mg/L (132umol/L)**
- Yes: Continue acetylsalicylic acid and check ALT at 12-hourly intervals. Other parameters are measured as indicated
- No: Commer acetylsalicylic acid

** ALT < 50U/L, or static and paracetamol concentration < 10mg/L (66umol/L)**
- Yes: Continue acetylsalicylic acid and check ALT at 12-hourly intervals. Other parameters are measured as indicated
- No: Commer acetylsalicylic acid
Acetylcysteine

- Calculation based on actual body weight to the nearest 10kg
- Ceiling weight of 110kg

* Assuming concentration of acetylcysteine is 200 mg/mL.
† Note: All patients weighing greater than 110 kg should be dosed according to a bodyweight of 110 kg.
Acute Liver Injury and Hepatotoxicity

• Acetylcysteine should be continued until:
  – The patient is clinically improving,
  – ALT levels are decreasing,
  – The international normalised ratio (INR) is improving < 2
  – Paracetamol concentration is less than 10 mg/L (66 μmol/L).

• Regular clinical review and 12-hourly (or more frequent) blood tests are recommended if there is clinical deterioration.

• A markedly prolonged INR is common in patients with severe hepatotoxicity and correction is not required, unless there is evidence of bleeding.

• Avoid correction of INR until discussion with a Liver Transplant Unit.
When to call the liver unit

A liver transplant unit should be consulted if any of the following criteria are met:

- INR >3.0 at 48 hours or >4.5 at any time;
- oliguria or creatinine >200 μmol/L;
- persistent acidosis (pH < 7.3) or arterial lactate >3 mmol/L;
- systolic hypotension with blood pressure less than 80 mmHg, despite resuscitation;
- hypoglycaemia;
- severe thrombocytopenia;
- encephalopathy of any degree, or any alteration of consciousness (Glasgow coma scale <15) not associated with co-ingestion of sedatives.
Paediatric accidental liquid paracetamol ingestion

• Children 6 years and under
• If they have ingested greater than 200mg/kg measure a paracetamol concentration any time after 2 hours.

• Management:
  – 2 (to 4) hour concentration is below 150mg/L (1000µmol/L), acetylcysteine **is not** required.
  – If the paracetamol level at 2 hours is greater than 150mg/L (1000µmol/L) level repeated at 4 hours
  – 4 hour level is > 150mg/L commence acetylcysteine
Children between 1-5 years are thought to be less susceptible to toxicity than older children and adults.

It is estimated <5% of children with paracetamol level above the nomogram line will have transiently abnormal LFT

**Earlier peak levels because of short absorption half life and shorter elimination half life**

Elimination half life increases with size

Modelled 1000 children - in the simulation maximum concentration was reached **before 2 hrs in 95% of children**.

Compared to 121 children (NO children had a level > 200mg/L at 4 hours)

Adults in the model 4x as many individuals with T1/2 > 4 hrs compared with 1 yr olds

Anderson’s paper recommends a 2 hour level of 225 mg/L (1500µmol/L) but to **increase the safety threshold in children a consensus was reached to lower this level at 2 hours to 150mg/L (1000µmol/L) and to furthermore repeat a level at 4 hours.**

Paediatric (<6yrs) liquid paracetamol ingestion

- A 2 hour level should only be utilised in a well-child with an isolated paracetamol ingestion, in all other cases a 4 hour level should be performed.
- Furthermore for those children who present later than 4 hours post ingestion or in children older than 6 years of age then treat as per adult acute paracetamol exposure.
When to call PIC or a Toxicologist

- Very large overdoses:
  - Immediate release or modified release paracetamol overdoses of > 50 g or 1 g/kg (whichever is lower).
  - A very high paracetamol concentration, more than double the nomogram line.
- Intravenous paracetamol errors/ overdoses.
- Patients with hepatotoxicity (e.g. ALT > 1000 IU/L).

**Note:** These are situations where the risk of hepatotoxicity may be greater, the optimum advice is potentially changing and where it may be most useful to seek advice.
Australian Toxicology Monitoring Study (ATOM) –
Australian Paracetamol Project (APP)

- Prospective Observational Study
- Recruit patients through calls to the NSW and QLD PIC
- Inclusion:
  - > 14yrs
  - Ingestion of > 35g of paracetamol
  - Paracetamol level > 2000umol/L (300mg/L) at anytime
  - Ingestion of > 10g of sustained release paracetamol
  - Any patients with deranged LFT: AST > 500IU/L, ALT > 500IU/L
    (that is 10X the upper limit of normal)
COMMENTS or QUESTIONS

As it's your first day we're going to start you on something easy.
